

Module UNO.CLS (OpenOffice.org)

The object-oriented interface support for ooRexx is realized by calling or requiring the ooRexx module UNO.CLS, which defines public routines, classes and the environment symbol .UNO (a directory containing UNO objects). You can get at that support in one of two ways:

```
call UNO.CLS /* make UNO-support for ooRexx available */
```

or

```
::requires UNO.CLS /* make UNO-support for ooRexx available */
```

UNO.CLS is based upon the BSF4Rexx support for ooRexx and therefore requires the ooRexx module BSF.CLS. As a consequence all of the BSF4Rexx features are available as well.

Some of the UNO subfunctions are made available as instance methods of the proxy class UNO_PROXY, prepended with the string "uno."

The ooRexx class UNO_PROXY is used for representing UNO Java (class) objects. Its instances are proxy objects which forward received messages to the Java side for invocation.

Although this module can be used for interfacing with OpenOffice, it generically supports interfacing with UNO and can as such be used to drive any UNO based application.

```
/* create desktop service object, get its Desktop interface object
and its ComponentLoader interface object (to load documents) */
ocl=UNO.createDesktop()->XDesktop-XComponentLoader

/* define document URL, also file-, ftp- or http-URL possible */
url = "private:factory/swriter" /* "swriter": text component */
otc=ocl~loadComponentFromURL(url, "_blank", 0, .UNO~noProps)

/* get text document's document interface object and retrieve */
oText=otc~XTextDocument~getText /* its text object */
oText~setString("Hello world from ooRexx on" date("s") time())

/* show services, i.e., the type of the component, interfaces */
str=ppd("services: " otc~uno.getServiceNames, " ", "0a"x) "0a"x
ppd(" interfaces: " otc~uno.getInterfaceNames, " ", "0a"x)
.bsf.dialog~messageBox(str, "Services/Interfaces", "information")

::requires UNO.CLS -- get UNO support
```

Public Routines

1. `decodeUrl(url)` returns the decoded url (all characters escaped as %xy sequences are replaced by their single characters)
2. `encodeUrl(url)` returns the encoded url (see definition of URL characters, those not allowed are escaped as %xy hex-strings)
3. `ppd(string [,delimiter] [,replacement])` returns the string in a form, where each delimiter (blank by default) is replaced by the replacement string (default: line.separator || TAB)
4. `uno.areSame(unoProxy1, unoProxy2)` returns .true, if both UNO proxy objects refer to the same UNO object, .false else
5. `uno.connect([unoURL] [,xComponentContext])` returns the xContext if no object of the local installation (use it to retrieve its `ServiceManager`) or returns the `remoteObject` in case the optional `unoURL` was supplied; the optional `xComponentContext` allows to determine which (already established) connection to use
6. `uno.convertFromUrl(url)` returns the file encoded as an url as a fully qualified file name matching the rules of the host operating system
7. `uno.convertToUrl(url)` returns the platform dependent, fully qualified file name encoded as an url
8. `uno.createArray(...)` same arguments as `bsf.createArray()`, but returns an instance of `UNO_ARRAY_PROXY`, which makes sure that the array objects are wrapped up using the public routine `uno.wrap(...)`
9. `uno.createDesktop([xContext])` returns the local OpenOffice desktop object or the desktop object of the xContext argument, if supplied

10. `uno.findInterfaceWithMember(o, name [,bString] [,howMany])` searches the service object o for an interface that contains name as a member. Returns the interface object, if bString is .false (default) or the fully qualified UNOIDL interface name else. In the latter case howMany (default: 1) determines how many interfaces (delimited with a blank) having a matching member should be returned; a value smaller than 1 returns all matching interfaces.
11. `uno.getCachedInterfaceName(name [,delimiter])` returns a string with the fully qualified, mixed-case UNO_IDL name of the interface denoted by name, which can be in uppercase and unqualified (the string after the last dot). Should there be multiple fully qualified interfaces matching an unqualified name, then the string contains them all delimited with the delimiter string (defaults to blank).
12. `uno.getCell(xSheet, nameAddress)` returns the (upper-left) cell object of the spreadsheet xSheet using an alphanumeric address (e.g. "B5")
13. `uno.getCell(xSheet, x, y)` returns the cell object of the spreadsheet xSheet using the 0-based column (x) and row (y) coordinates.
14. `uno.getDefinition(o)` returns a string which encodes all UNOIDL information (see table "UNOIDL String Encodings"). o can be a service object or an UNO_IDL string.
15. `uno.getInterfaceNamesViaReflection(o)` returns a blank delimited string of the interface names that are defined for the service object o using the UNOIDL definitions via reflection
16. `uno.getProperties(o)` returns a blank delimited, encoded string (see table "UNO_IDL Encodings") with all defined properties for the service object o
17. `uno.getScriptContext()` returns a UNO proxy, if the ooRexx script was invoked by OpenOffice, .nil else. The UNO proxy object has the following methods, returning context related UNO proxy objects:
 - getDocument (the document service object, an XModel),
 - getDesktop (the desktop service object, an XDesktop), and
 - getComponentContext (the context object, an XComponentContext).
18. `uno.getScriptContextVersion()` returns a string denoting the ooRexx Script framework version
19. `uno.getServiceNamesViaReflection(o)` returns a blank delimited string of the service names that are defined for the service object o using the UNOIDL definitions via reflection.
20. `uno.getTypeName(o)` returns o's UNO datatype name (see table "UNO Datatype Names")
21. `uno.getXTypeProviderTypeNames(o)` returns a blank delimited string of the interface names that the object o implements. Note: it is possible that not all implemented interfaces are reported by the object o! You can exploit the UNOIDL definitions instead using the routines `uno.getDefinition(o)` or `uno.getInterfaceNamesViaReflection(o)`.
22. `uno.loadClass(className [,idx])` imports and returns the `className` UNO class object; in addition the uno proxy gets stored in the .UNO directory using the (uppercased) `idx` as index (defaults to the unqualified `className`, i.e., the class name after the last dot).
23. `uno.queryInterfaceName(o, name)` returns the fully qualified interface name of o which contains name (can be unqualified and in any case) as a member, returns blank "" string, if not found
24. `uno.queryInterfaceObjectByName(o, name)` returns the interface object for o which contains name (can be unqualified and in any case) as a member, returns .nil, if not found
25. `uno.queryServiceName(o, name)` returns the fully qualified service name of o which contains name (can be unqualified and in any case) as a member, returns blank "" string, if not found
26. `uno.setCell(xSheet, nameAddress, content)` sets the (upper-left) cell object of the spreadsheet xSheet using an alphanumeric address (e.g. "B5") using `setFormula(content)` which works for strings and formulas
27. `uno.setCell(xSheet, x, y, content)` sets the cell object of the spreadsheet xSheet using the 0-based column (x) and row (y) coordinates using `setFormula(content)` which works for strings and formulas
28. `uno.wrap(bsfObject)` returns an UNO proxy object, if `bsfObject` is a BSF (Java) proxy object

Class UNO_PROXY

This is the ooRexx proxy class for representing UNO Java proxy classes. ooRexx messages sent to its instances cause the invocation of the appropriate methods. Most of the methods starting with uno. are pass-through methods and their arguments (except for the first one, which is the UNO_PROXY object itself) are documented in the "Public Routines" section. This class is able to handle messages that are named after UNO interfaces (either the fully qualified name or the unqualified name, i.e., the name after the last dot; the unqualified name must start with the letter "X" to qualify as an interface name), returning the appropriate interface object.

UNO_PROXY'S INSTANCE METHODS

1. `uno.bsfObject` returns the wrapped BSF proxy object
2. `uno.findInterfaceWithMember(name[, bString] [,howMany])` see public routine
3. `uno.getDefinition` see public routine
4. `uno.getInterfaceNames` see public routine `...ViaReflection`
5. `uno.getProperties` see public routine
6. `uno.getServiceNames` see public routine `...ViaReflection`
7. `uno.getTypeName` see public routine
8. `uno.getXTypeProviderTypeNames` see public routine
9. `uno.isSame(otherProxyObject)` returns .true, if this proxy object is the same as otherProxyObject, .false else
10. `uno.queryInterfaceName(name)` see public routine
11. `uno.queryInterfaceObjectByName(name)` see public routine
12. `uno.queryServiceName` see public routine

Class UNO_ARRAY_REFERENCE

UNO_ARRAY_REFERENCE is a subclass of UNO_PROXY that allows interacting with Java array objects (stored in the BSF registry) as if they were ooRexx arrays (e.g. index values start with 1, and the ooRexx array methods AT, [], DIMENSION, ITEMS, MAKEARRAY, PUT, []=, SUPPLIER are available). If returning an object from the array it will get wrapped up as an UNO_PROXY.

The public routine `uno.wrap` will use this class to create the ooRexx proxy object, if it detects that the supplied proxy object refers to an array object (i.e., it is an instance of the class `BSF_ARRAY_REFERENCE`).

Class UNO_DIRLIKE

UNO_DIRLIKE is the superclass for the public classes UNO_CONSTANTS and UNO_ENUM which allow easy access to the definitions either by name or value employing the ooRexx directory class semantics.

UNO_DIRLIKE'S INSTANCE METHODS

1. `directory` returns a copy of the directory (`unoDirectory`) that stores all definitions
2. `entry(index)` returns the item associated with index or .nil, if index is not used
3. `hasEntry(index)` returns .true if an item is associated with index, .false else
4. `init(unoIdl_className)` retrieves the UNOIDL definitions of unoIdl_className and if successful, sends the message `setup` to the newly created instance (implemented in the subclass), which sets up the `unoDirectory` and `unoNameQueue` accordingly
5. `makearray` returns an array of names in `unoNameQueue` order
6. `nameQueue` returns a copy of the queue (`unoNameQueue`) which contains the names in definition order

- supplier** returns a supplier where the index values follow the `unoNameQueue` order
- unoDirectory** returns the directory that stores all definitions, a *private* method (message needs to be sent to `self` to succeed)
- unoidl_definition** returns the string which encodes all UNOIDL information (see table "UNO_IDL Encodings")
- unoidl_name** returns the fully qualified UNOIDL name (a string)
- unoidl_typeName** returns the UNOIDL type name (a string, see table "UNO Datatype Names")
- unoNameQueue** returns the queue which contains the names in definition order, a *private* method (message needs to be sent to `self` to succeed)

Public Class UNO_CONSTANTS

UNO_CONSTANTS is a subclass of **UNO_DIRLIKE** which is able to store all defined constants in an ooRexx directory object. Sending the name of a constant to an instance of this class returns the associated numeric value or `.nil`, if the constant name is not defined. In addition it is possible to send the numeric value to it, which would return the constant's name or `.nil`, if no constant is defined for that value.

See also the public routines: `bsf.getConstant(JavaClassName, fieldName)` and `bsf.wrapStaticFields(unoidl_className)`

UNO_CONSTANTS' INSTANCE METHODS

- decode(number)** returns a blank delimited string listing the constant names that together yield `number`.
- encode(string)** returns a number representing the constants of the blank delimited `string`, which may consist of constant names, constant numeric values or a mixture of both.
- makestring** encodes all its constants as the required string value
- setup** *private* method which sets up the object by processing the UNOIDL definition of the constants, invoked via the superclass' constructor.

Public Class UNO_ENUM

UNO_ENUM is a subclass of **UNO_DIRLIKE** which is able to store all individual enumeration objects in an ooRexx directory object. Sending the name or its numeric value to an instance of this class returns the associated enum object or `.nil`, if the enumeration name is not defined. An enum object returned by this class possesses the methods `name` and `value`.

See also the public routines: `bsf.getConstant(JavaClassName, fieldName)` and `bsf.wrapStaticFields(unoidl_className)`

UNO_ENUM'S INSTANCE METHODS

- setup** *private* method which sets up the object by processing the UNOIDL definition of the constants, invoked via the superclass' constructor.
- makestring** encodes all its enum values as the required string value

Environment Object .UNO (A Directory Object)

UNO.CLS will initialize a directory object accessible via the environment symbol `.UNO` to store important UNO/OOo objects. In addition it serves as a cache for interface class objects that have been instantiated while running an application as well as for classes that were loaded with the help of the public routine `uno.loadClass(unoidl_className [,idx])`. The following table lists the initial content of this directory object.

Index	Description
ANY	<code>com.sun.star.uno.Any</code>
ANYCONVERTER	<code>com.sun.star.uno.AnyConverter</code>
BEXTENDSEARCH	Boolean value determining whether reflection should exploit the UNOIDL definitions if interface not found in

	XTypeProvider list, preset to: <code>.true</code>
BOOTSTRAP	<code>com.sun.star.comp.helper.Bootstrap</code>
FILE.SEPARATOR	Operating system dependent value retrieved from the respective <code>java.lang.System</code> property.
LINE.SEPARATOR	Operating system dependent value retrieved from the respective <code>java.lang.System</code> property.
NOPROPS	Empty array object of type <code>com.sun.star.beans.PropertyValue</code> ; use, if property array must be given as an argument, but no properties need to be set.
PROPERTYVALUE	<code>com.sun.star.beans.PropertyValue</code>
RGFREFLECTUNO	<code>org.oorexx.uno.RgfReflectUNO</code>
UNORUNTIME	<code>com.sun.star.uno.UnoRuntime</code>
VERSION	<code>UNO.CLS</code> version (a string)
XINTERFACES	Directory object containing a mapping of fully and unqualified interface names to their exact cased, fully qualified UNOIDL name.
XINTERFACES.DUPES	Relation object containing a mapping of unqualified interface names (which got already used in the XINTERFACES directory) to their exact cased, fully qualified UNOIDL name (as they cannot be stored with the XINTERFACES directory).

Table "UNO Datatype Names"

The following names are derived from the names defined by the enum `com.sun.star.uno.TypeClass` and prepended with the string `"UNO_"`.

"UNO_ANY"	"UNO_ENUM"	"UNO_MODULE"	"UNO_TYPE"
"UNO_ARRAY"	"UNO_EXCEPTION"	"UNO_PROPERTY"	"UNO_TYPEDEF"
"UNO_BOOLEAN"	"UNO_FLOAT"	"UNO_SEQUENCE"	"UNO_UNION"
"UNO_BYTE"	"UNO_HYPER"	"UNO_SERVICE"	"UNO_UNKNOWN"
"UNO_CHAR"	"UNO_INTERFACE"	"UNO_SHORT"	"UNO_UNSIGNED_HYPER"
"UNO_CONSTANT"	"UNO_INTERFACE_ATTRIBUTE"	"UNO_SINGLETON"	"UNO_UNSIGNED_LONG"
"UNO_CONSTANTS"	"UNO_INTERFACE_METHOD"	"UNO_STRING"	"UNO_UNSIGNED_SHORT"
"UNO_DOUBLE"	"UNO_LONG"	"UNO_STRUCT"	"UNO_VOID"

Table "Mapping UNO to Java Datatypes"

UNO Datatype	Java Datatype
UNO_ANY	<code>com.sun.star.uno.Any</code> or <code>java.lang.Object</code>
UNO_VOID	<code>void</code>
UNO_BOOLEAN	<code>boolean</code>
UNO_BYTE (8-bit)	<code>byte</code>
UNO_CHAR (16-bit)	<code>char</code>
UNO_SHORT (16-bit)	<code>short</code>
UNO_UNSIGNED_SHORT (16-bit)	<code>short</code>
UNO_LONG (32-bit)	<code>int</code>
UNO_UNSIGNED_LONG (32-bit)	<code>int</code>
UNO_HYPER (64-bit)	<code>long</code>
UNO_UNSIGNED_HYPER (64-bit)	<code>long</code>
UNO_FLOAT	<code>float</code>
UNO_DOUBLE	<code>double</code>

Table "UNOIDL String Encodings"

The following table defines the string encodings of the fundamental

UNO datatypes as returned e.g. by the method (or public routine) `getDefinition`. Definition groups are delimited by a blank " ", Constituents of a definition group are delimited with a vertical bar "|", elements of a collection are delimited with a comma ",". Additional characters used as delimiters for parsing are highlighted in yellow. Items enclosed in square brackets ("[]") are optional and can be left out. An ellipsis ("...") indicates that the preceding type/group may be repeated.

Encoding Definition
UNO_CONSTANTS fully-qualified-name UNO_Datatype member-name value... <i>Remark:</i> the following "UNO_Datatype" is one of the following: UNO_BOOLEAN, UNO_BYTE, UNO_SHORT, UNO_UNSIGNED_SHORT, UNO_LONG, UNO_UNSIGNED_LONG, UNO_HYPER, UNO_UNSIGNED_HYPER, UNO_FLOAT, UNO_DOUBLE.
UNO_ENUM fully-qualified-name default-value member-name value... <i>Remark:</i> the individual values are always of type UNO_LONG.
UNO_EXCEPTION fully-qualified-name member-name datatype... UNO_INTERFACE fully-qualified-name member-name member-definition... where "member-definition" is one of: • UNO_ATTRIBUTE [READONLY] datatype... • UNO_METHOD [ONEWAY] retValue-datatype [argName:datatype[...]] [exception[...]]
UNO_MODULE fully-qualified-name member-name UNO_Datatype...
UNO_SERVICE fully-qualified-name [implName] memberName definition... where "definition" is one of: • UNO_INTERFACE [OPTIONAL] defined_by_service • UNO_SERVICE [OPTIONAL] defined_by_service • UNO_PROPERTY [modifier[...]] datatype defined_by_service <i>Remark:</i> if a service object is reflected that implements more than one service definition, than the "fully-qualified-name" of that compound service is created by concatenating all service names with the plus sign (+). Each of these constituting service definitions (if available via reflection) is then used to create the entire definition of that "compound service" object in hand, documenting all defined interfaces, services and properties.
UNO_SINGLETON fully-qualified-name [old-style-servicename]
UNO_STRUCT fully-qualified-name memberName datatype...
UNO_TYPEDEF fully-qualified-name referenced-type UNO_Type
