

An Introduction to Procedural and Object-oriented Programming (ooRexx) 4

Abstract Datatype, Classes, Methods, Attributes,
Messages, Scopes, Generalizing Class Hierarchy,
Inheritance

Prof. Rony G. Flatscher

Datatype (DT)

- Datatype
 - Defines the set of acceptable values
 - Defines the allowable operations (e.g. adding, concatenating)
 - Example
 - Datatype **Birthday**
 - E.g. defines a valid date and a valid time
 - Allowable operations, e.g. change/query the values of the stored date and time
 - Datatype **Person**
 - E.g. defines first name, family name, salary
 - Allowable operations, e.g. changing the values for first name, family name, salary, increase salary

Datatype (DT)

Classic Rexx, Problems

- No means to *explicitly* define structures to represent a datatype
- No means to *explicitly* define operations which are only valid for a *specific* datatype
- Attempt to encode the structure with the help of
 - Strings
 - Stem-Variables

Datatype (DT)

Classic Rexx, Possible Solution 1

- Encoding with the help of **Strings**
 - E.g. data of type *Birthday*
 - "20050901 16:00"
 - "20080229 19:19"
 - E.g. data of type *Person*
 - "Albert Einstein 45000"
 - "Vera Withanynname 25000"
 - Processing only possible if the following is known to everyone
 - **Number** and **sequence** of the DT-"fields" (columns)
 - **Dimension** of the columns (variable, fixed width)
 - For instance encoded ASCII-files
 - Variable column width, hence a delimiting character necessary
 - E.g. "Comma Delimited Format"
 - Fixed column width

Datatype (DT)

Classic Rexx, Possible Solution 2

- Encoding with the help of **stems**

- E.g. data of type *Birthday*

- Collection of string encoded data with the help of stems

```
birth.1 = "20120901 16:00"
```

```
birth.2 = "20160229 19:19"
```

- Processing only possible if one knows the **number**, **sequence** *and* **width** of columns of the DT-"fields", e.g. `SysFileTree()`

- **Structuring** and collection of the string encoded data with the help of stems

```
birth.1.eDate = "20120901"
```

```
birth.1.eTime = "16:00"
```

```
birth.2.eDate = "20160229"
```

```
birth.2.eTime = "19:19"
```

- Processing already possible, if one knows **only** the identifiers (names) of the individual DT-"fields"!

Datatype (DT)

Classic Rexx, Possible Solution 3

- Encoding with the help of **stems**

- E.g. data of type *Person*

- **Structuring** with the help of stems

```
pers.eFirstName = "Albert"
```

```
pers.eLastName  = "Einstein"
```

```
pers.eSalary    = "45000"
```

and

```
pers.eFirstName = "Vera"
```

```
pers.eLastName  = "Withanyname"
```

```
pers.eSalary    = "25000"
```

- If using stems one **must** introduce an additional index in order to be able to store both persons above, independent of each other!
- The latter assignments ("Vera") would replace ("overwrite") the first ones ("Albert")

Datatype (DT)

Classic Rexx, Discussion of Possible Solutions

- DT structure
 - Encoding in strings and stems
 - Crook, as implementation dependent!
 - Error prone
- DT operations
 - No possibility to define operations for datatypes!
 - Functions and procedures must be defined on their own
 - Direct access to strings and stems **must** be realized via **EXPOSE** statements
 - Problems with scopes, source of errors
- Insulating ("Encapsulating") of individual DT extensions ("instances") not possible

Abstract Datatype (ADT)

- Abstract Datatype
 - **Schema** for the implementation of datatypes
 - Definition of **Attributes**
 - Results in the data structure
 - Definition of **Operations** ("Behaviour")
 - Functions, Procedures
 - Internal datastructures and values are usually
 - Not visible from the "outside"
 - Not directly editable from the "outside"
 - **Encapsulation !**
 - **Schema** must be implemented in an *appropriate* Programming language
 - Classic Rexx is not really *appropriate* for this
 - Object Rexx *is* - as any other object-oriented - programming language appropriate

Abstract Datatype (ADT)

Implementation with Object Rexx

- Abstract Datatype
 - **Schema** for the implementation of datatypes
 - **::CLASS** directive
 - Definition of **attributes** and therefore the internal datastructure
 - **EXPOSE** statement **within** methods or
 - **::METHOD** directive with the keyword **ATTRIBUTE**
 - Definition of **operations** (functions, procedures)
 - **::METHOD** directive
 - Instance of classes ("object")
 - Individual, unambiguously distinguishable instantiations of the same type
 - Possesses all the same attributes (constitute the datastructure as defined in the class) and operations ("methods of the class")

Abstract Datatype (ADT)

Example: Definition of an ADT

- Object Rexx implementation of the ADT *Birthday*

```
/**/
```

```
::CLASS Birthday  
::METHOD date ATTRIBUTE  
::METHOD time ATTRIBUTE
```

- Object
 - Instance (extension) of an ADT, i.e., of a class
 - Uniquely distinguishible from other objects (even) of the same type
 - Creation: sending the message **NEW** to a class
 - Accessing the class via its environment symbol
 - Dot, immediately followed by the class identifier (name of the class), e.g.

```
object1 = .String~NEW("hallo") /* Object Rexx version */  
object2 = "hallo" /* classic Rexx version */
```

Object Rexx

Messages

- **Interaction** (activating of functions/procedures) **with objects** (instances) **exclusively** via messages, which are sent to objects
 - Names of messages are the names of the methods, that should be invoked
 - Message operator ("*twiddle*") is the tilde character: ~
 - E.g. "ABC" ~REVERSE yields: CBA
 - "Cascading" messages, two twiddles: ~ ~
 - E.g. "ABC" ~~REVERSE yields (**attention!**): ABC
 - Sent messages activate the respective methods of the receiving object, result is **always** the receiving object!
 - Therefore multiple messages intended for the same object can be "cascaded" one after the other
 - Execution of messages: left to right

Abstract Datatype (ADT)

Example: Using of an ADT

- Object Rexx implementation of the ADT *Birthday*

```
/**/  
g1 = .Birthday~New  
g1~Date= "20120901"  
g1~Time= "16:00"  
g2=.Birthday~New~~"Date="( "20160229" )~~"Time="( "19:19" )  
SAY g1~date g2~date g1~time g2~time
```

```
::CLASS Birthday  
::METHOD date ATTRIBUTE  
::METHOD time ATTRIBUTE
```

Output:

```
20120901 20160229 16:00 19:19
```

Abstract Datatype (ADT)

Example: Using of an ADT, 2

- Object Rexx implementation of the ADT *Birthday*

```
/**/  
g1 = .Birthday ~New  
g1 ~Date = "20120901"  
g1 ~Time = "16:00"  
g2 = .Birthday ~New ~~"Date=" ( "20160229" ) ~~"Time=" ( "19:19" )  
SAY g1~date g2~date g1~time g2~time
```

```
::CLASS Birthday  
::METHOD date ATTRIBUTE  
::METHOD time ATTRIBUTE
```

Output:

```
20120901 20160229 16:00 19:19
```

Scope (1)

- Scope
 - Determines the visibility of labels, variables, classes, routines, methods and attributes
- Cf. article
 - <http://wi.wu-wien.ac.at/rgf/rexx/orx07/Local.pdf>
- **"Standard Scope"**
 - Determines which labels are visible
 - Labels are only visible within a program (until the end of the program **or** until the first directive led in by a double colon **::**, whatever comes first)
 - Labels within of **::ROUTINE** and **::METHOD** directives are only visible within these directives

Scope (2)

- **"Procedure Scope"**
 - Determines, which variables of the caller are visible (accessible) from within the called procedure/function
 - Labels, **without** a **PROCEDURE** statement
 - All variables of the calling part of the program are accessible
 - Labels, followed by a **PROCEDURE** statement
 - Variables of the calling part of the program are **not** accessible (are hidden)
 - **"Local scope"**
 - **But:** with the help of the **EXPOSE** statement which may immediately follow a **PROCEDURE** statement one can deliberately define direct access to variables of the calling part of the program

Scope (3)

- "Program Scope"
 - Determines that all classes and routines defined in a program are accessible
 - **Local classes** and **routines** cannot be hidden/overwritten
 - Classes and routines can be defined to be **public**
 - In addition, this scope determines, that *public classes* and *public routines* of called or required (**::REQUIRES** directive) programs become accessible
 - **Attention!**
 - If *different* programs are called one after the other, and contain *public classes* or *public routines* with the *same names*, then those classes/routines are accessible that are defined in the *last called program*

Scope (4)

- **"Routine Scope"**
 - Defines its own scope for
 - Labels ("standard scope") and
 - Variables ("procedure scope")
 - Accessing classes and routines is determined by the "program scope"

Scope (5)

- **"Method Scope"**
 - Defines its own scope for
 - Labels ("standard scope") and
 - Variables ("procedure scope")
 - Accessing classes and routines is determined by the "program scope"
 - Attributes
 - Within a method it is possible to use the **EXPOSE** statement (immediately following the method directive) to list those attributes of the class which should be made directly available for access from within the method.
 - Defining attributes and their access methods can be alternatively carried out by using an **ATTRIBUTE** method directive.

Scope (6)

- "Method Scope" (continued)
 - Determines *which* attributes can be accessed *directly* from within a method
 - There are two types of scopes which determine the accessibility of attributes
 - Attributes, which are defined in methods assigned to classes
 - Methods defined after a class directive
 - Share the same set of ("instance") attributes
 - Attributes, which are defined in "free running methods"
 - Methods which are defined *before* a class directive
 - Share the same set of ("free running") attributes
 - *Hint*: accessing free running methods is possible via the environment symbol **.METHODS** from within the program where there are defined

Overview of Scopes

- Rexx und Object Rexx
 - Standard scope
 - Labels, variables
 - Procedure scope
 - Variables in procedures/functions
- Object Rexx
 - Program scope
 - Accessing local and public classes and routines of called/required programs
 - Routine scope
 - Standard+procedure+program scope
 - Method scope
 - Standard+procedure+program plus accessibility of attributes
 - Instance methods: methods, which are defined for a class ("instance" attributes)
 - Free running methods: methods, which are defined **before** any class directive ("free running" attributes)

Abstract Datatype "Person"

Implementation in Object Rexx, 1

```
/**/
```

```
p1 = .Person~New; p1~firstName= "Albert";  
p1~familyName= "Einstein"; p1~salary=45000
```

```
p2=.Person~New~~"firstName="( "Vera" )~~"salary="( "25000" )  
p2~~"familyName="( "Withanyname" )
```

```
SAY p1~firstName p1~familyName p1~salary
```

```
SAY p2~firstName p2~familyName p2~salary
```

```
SAY "Total costs of salaries:" p1~salary + p2~salary
```

```
::CLASS Person  
::METHOD firstName ATTRIBUTE  
::METHOD familyName ATTRIBUTE  
::METHOD salary ATTRIBUTE
```

Output:

```
Albert Einstein 45000
```

```
Vera Withanyname 25000
```

```
Total costs of salaries: 70000
```

Abstract Datatype "Person"

Implementation in Object Rexx, 2

```
/**/
```

```
p1 = .Person~New; p1~firstName= "Albert";  
p1~familyName= "Einstein"; p1~salary= "45000"
```

```
p2=.Person~New~~"firstName="( "Vera" )~~"salary="( 25000 )  
p2~~"familyName="( "Withanyname" )
```

```
SAY p1~firstName p1~familyName p1~salary p2~firstName
```

```
SAY p1~firstName p1~salary p1~~increaseSalary(10000)~salary
```

```
::CLASS Person  
::METHOD firstName ATTRIBUTE  
::METHOD familyName ATTRIBUTE  
::METHOD salary ATTRIBUTE  
::METHOD increaseSalary  
EXPOSE salary  
USE ARG increase  
salary = salary + increase
```

Output:

```
Albert Einstein 45000 Vera
```

```
Albert 45000 55000
```

Creating Objects

- Creating new objects
 - The **NEW** message is sent to the class
 - Result is a reference to an object (an instance) of the class
- **If** there is a method with the name **INIT** defined for a class, then this method will be invoked, before control returns. This is realized by way of sending the message **INIT** to the newly created object from within the **NEW** method.
 - If the message **NEW** received arguments, these will be forwarded **in the same sequence** with the **INIT** message to the newly created object
- The **INIT** method is also called ***"constructor"***

Abstract Datatype "Person"

Implementation in Object Rexx, Constructor

```
/**/  
p1 = .Person~New("Albert", "Einstein", "45000")  
p2 = .Person~New("Vera", "Withanyname", 25000)  
SAY p1~firstName p1~familyName p1~salary p2~firstName  
SAY p1~firstName p1~salary p1~~increaseSalary(10000)~salary  
::CLASS Person  
::METHOD INIT  
  EXPOSE firstName familyName salary  
  USE ARG firstName, familyName, salary  
::METHOD firstName ATTRIBUTE  
::METHOD familyName ATTRIBUTE  
::METHOD salary ATTRIBUTE  
::METHOD increaseSalary  
  EXPOSE salary  
  USE ARG increase  
  salary = salary + increase
```

Output:

```
Albert Einstein 45000 Vera  
Albert 45000 55000
```

Deleting of Objects

- Objects are automatically deleted from the runtime system, if they are not referenced anymore (becoming "garbage")
 - **If** there is a method named **UNINIT** defined for a class, then this method will be invoked, right before the unreferenced object gets deleted. This will be invoked by the runtime system by sending the object the message **UNINIT**.
- The **UNINIT** method is called *"destructor"*

The Rexx "DROP" statement

- **DROP** statement
 - The **DROP** statement allows the explicit deleting of a variable
 - If a variable is destroyed its reference to an existing object is removed
 - There is still the possibility that there are other variables which still possess references to such an object

Abstrakter Datentyp "Person"

Umsetzung in Object Rexx, Destruktor

```
/**/  
p1 = .Person~New("Albert","Einstein","45000")  
p2 = .Person~New("Vera","Withanyname",25000)  
SAY p1~firstName p1~familyName p1~salary p2~firstName  
SAY p1~firstName p1~salary p1~~increaseSalary(10000)~salary  
DROP p1; DROP p2; CALL SysSleep( 15 ); SAY "Finish."  
::CLASS Person  
::METHOD INIT  
  EXPOSE firstName familyName salary  
  USE ARG firstName, familyName, salary  
::METHOD UNINIT  
  EXPOSE firstName familyName salary  
  SAY "Object: <"firstName familyName salary"> is about to be destroyed."  
::METHOD firstName      ATTRIBUTE  
::METHOD familyName    ATTRIBUTE  
::METHOD salary         ATTRIBUTE  
::METHOD increaseSalary  
  EXPOSE salary  
  USE ARG increase  
  salary = salary + increase
```

Output, for example:

```
Albert Einstein 45000 Vera  
Albert 45000 55000  
Object: <Vera Withanyname 25000> is about to be destroyed.  
Finish.  
Object: <Albert Einstein 55000> is about to be destroyed.
```

Abstract Datatype (ADT)

Implementation in Object Rexx

- Abstract Datatype (Repetition)
 - **Schema** for the implementation of datatypes
 - Definition of **Attributes**
 - Results in the data structure
 - Definition of **Operations** ("Behaviour")
 - Functions, Procedures
 - Internal datastructures and values are usually
 - Not visible from the "outside"
 - Not directly editable from the "outside"
 - **Encapsulation !**
 - **Schema** must be implemented in an *appropriate* Programming language
 - Classic Rexx is not really *appropriate* for this
 - Object Rexx *is* - as any other object-oriented - programming language appropriate

Classification Tree (Generalization Hierarchy)

- Generalization Hierarchy, "Classification Tree"
 - Allows **classification of instances** (Objects), e.g. from biology
 - **Ordering of classes in superclasses and subclasses** (schemata)
 - Subordered classes ("subclasses") **inherits** all properties of all superclasses up to and including the root class
 - Subclasses **specialize** in one way or the other the superclass(es)
 - "Defining of differences"
 - Sometimes it may make sense, that a subclass specializes directly more than one superclass at the same time ("**multiple inheritance**")
 - Example: Classes representing landborn and waterborn animals, where there exists a class "amphibians", which inherits directly from the landborn and waterborn animals

Object Rexx: Classification Tree, 1

- Prefabricated "class tree"
 - Root class of Object Rexx is named "Object"
 - All user defined classes are assumed to specialize the class "Object", if no superclass is explicitly given
 - Single and multiple inheritance possible

Object Rexx: Classification Tree, 2

- Search order
 - Conceptually, the object receiving a message, starts searching for a method by the name of the received message and if found invokes it with the supplied arguments
 - If such a method is not found in the class, from which the object is created, then the search is continued in the direct superclass up to and including the root class
 - If the method is not even found in the root class "**Object**", then an error exception is thrown ("Object does not understand message")
 - If there is a method named **UNKNOWN** defined, then instead of creating an exception the runtime system will invoke that method, supplying the name of the unknown method and its arguments, if any were supplied with the message

Object Rexx: Classification Tree, 2

- Search order (continued)
 - For the purpose of searching there are special, pre-set variables which are **only available from within methods**
 - **super**
 - Always contains a reference to the immediate superclass
 - Allows re-routing the starting class for searching for methods to the superclass
 - **self**
 - Always contains a reference to the object for which the method got invoked
 - This way it becomes possible to send messages to the object from within a method
 - **super** and **self** determine the class, where the search for methods starts which carry the same name as the message

Example "Dog", 1

- Problem description
 - "Animal SIG" keeping dogs
 - Normal dogs
 - Little dogs
 - Big dogs
 - All dogs possess a name and are able to bark
 - Normal dogs bark "Wuff Wuff"
 - Little dogs bark "wuuf"
 - Big dogs bark "WUFFF! WUFFF!! WUFFF!!!"
 - Define appropriate classes taking advantage of inheritance (search order)

Example "Dog", 2

- Definition of a class "**Dog**", which possess all properties which are common to all types of dogs

```
/**/  
h1 = .Dog ~NEW ~"NAME=" ( "Sweety" ) ~Bark
```

```
::CLASS Dog  
::METHOD Name ATTRIBUTE  
::METHOD Bark  
SAY self~Name": "Wuff Wuff"
```

Output:

```
Sweety: Wuff Wuff
```

Example "Dog", 3

- Definition of a class "**BigDog**", which possesses all properties common to all big dogs

```
/**/  
h1 = .Dog      ~NEW ~~"NAME=" ("Sweety")  ~Bark  
      .BigDog  ~NEW ~~"NAME=" ("Grobian") ~Bark  
::CLASS Dog SUBCLASS Object  
::METHOD Name      ATTRIBUTE  
::METHOD Bark  
      SAY self~Name ":" "Wuff Wuff"  
::CLASS BigDog SUBCLASS dog  
::METHOD Bark  
      SAY self~Name ":" "WUFFF! WUFFF!! WUFFF!!!"
```

Output:

Sweety: Wuff Wuff

Grobian: WUFFF! WUFFF!! WUFFF!!!

Example "Dog", 4

- Definition of a class "**LittleDog**", which possesses all properties common to all little dogs

```
/**/  
.Dog~NEW      ~~"NAME=" ("Sweety")  ~Bark  
.BigDog~NEW   ~~"NAME=" ("Grobian") ~Bark  
.LittleDog~NEW ~~"NAME=" ("Arnie")  ~Bark  
  
::CLASS Dog  
::METHOD Name      ATTRIBUTE  
::METHOD Bark  
  SAY self~Name ":" "Wuff Wuff"  
  
::CLASS BigDog SUBCLASS dog  
::METHOD Bark  
  SAY self~Name ":" "WUFFF! WUFFF!! WUFFF!!!"  
  
::CLASS LittleDog SUBCLASS dog  
::METHOD Bark  
  SAY self~Name ":" "wuuf"
```

Output:

```
Sweety: Wuff Wuff  
Grobian: WUFFF! WUFFF!! WUFFF!!!  
Arnie: wuuf
```

Example "Dog", 5

- Definition of a class "**LittleDog**", which possesses all properties common to all little dogs

```
/**/  
.Dog~NEW      ~~"NAME=" ("Sweety")  ~Bark  
.BigDog~NEW   ~~"NAME=" ("Grobian") ~Bark  
.LittleDog~NEW ~~"NAME=" ("Arnie")   ~Bark  
::CLASS Dog          SUBCLASS Object  
::METHOD Name        ATTRIBUTE  
::METHOD Bark  
  SAY self~Name:" "Wuff Wuff" "-" self  
::CLASS BigDog      SUBCLASS dog  
::METHOD Bark  
  SAY self~Name:" "WUFFF! WUFFF!! WUFFF!!!" "-" self  
::CLASS "LittleDog" SUBCLASS dog  
::METHOD Bark  
  SAY self~Name:" "wuuf" "-" self
```

Output:

```
Sweety: Wuff Wuff - a DOG  
Grobian: WUFFF! WUFFF!! WUFFF!!! - a BIGDOG  
Arnie: wuuf - a LittleDog
```

Multithreading

- Multithreading
 - Multiple parts of a program execute at the *same time* (in parallel)
 - Possible problems
 - Data integrity (Object integrity)
 - Deadlocks
- Object REXX
 - **Inter** Object-Multithreading
 - *Different* objects (even of one and the same class) are sheltered from each other and can be active at the same time
 - **Intra** Object-Multithreading
 - ***Within*** an instance (an object) multiple methods can execute at the same time, if they are defined in *different classes*
